The Condition Factor, Length – Weight Relationship and Abundance of *Ilisha africana* (Block, 1795) from Nkoro River Niger Delta, Nigeria

J.F.N. Abowei
Department of Biological Sciences, Faculty of science, Niger Delta University, Wilberforce Island, Amassoma, Bayelsa State, Nigeria

**Abstract:** The condition factor, length-weight relationship and abundance of *Ilisha africana* from Nkoro River in the Niger Delta area of Nigeria was studied for a period of one year (January-December 2008). From a sample size of 113 specimens, K value was 0.999 and the exponential equation was $W_t = 0.05998 (T_L)^{2.719}$, indicating an isometric growth pattern. The highest catch was recorded in February (1.61), followed by March (1.00), January (0.90), December (0.60) and June (0.10). April, May, July, August, September, October and November recorded no catch during the study. The highest condition factor value (1.58) was recorded in February and the lowest (0.00) in September. The highest catch per unit effort (1.13) was recorded in stations 2 and 4, followed by station 1 (1.12) and station 3 (0.72 each). *Ilisha africana* in Nkoro river is in a stable environment and was more abundant in the dry season months of February, March, January and December.

**Key words:** Abundance, condition factor, *Ilisha africana*, length-weight relationship, Nkoro River and Nigeria

**INTRODUCTION**

*Ilisha africana* is a pelagic clupeiforms belonging to the family, pristigasteridae, found along beaches and offshore; also in lagoons and estuaries, penetrating into almost freshwater. Feeds on plankton, benthic invertebrates, fish and detritus. The species is distributed along, Atlantic, Pacific, and Indian oceans. Tropical oceans and in the freshwaters of South America and Southeast Asia. Externally distinguished from other sardines by their long anal fin, which has at least 30 fin rays; in nearly all members, the small pelvic fin is markedly displaced anteriorly that the tip of the (http://zipcodezoo.com/glossary/pectoral_fin.asp). Pectoral fin reaches or surpasses the vertical through the base of the pelvic fin. Species under genera Ilisha, Pellona and Pristigaster were formerly under family Clupeidae.

The family Pristigasteridae belongs to the Class Actinopterygii (ray-finned fishes ) and the Order Clupeiformes. It contains 9 genera and 37 species. It may be found in marine, brackish and freshwater environments but primarily marine. This family may be found from 40ºN to 35ºS and 115ºW to 150ºE. Typically found at an altitude of 0 to 978 meters (0 to 3,209 feet). Apart from being a cheap source of highly nutritious protein, it also contains other essential nutrients required by the body (Sikoki and Otabotokere, 1999). The fishery of the flat fish is highly commercial and marketed fresh, smoked or dried.

Condition factor compares the wellbeing of a fish and is based on the hypothesis that heavier fish of a given length are in better condition (Bagenal and Tesch, 1978). Condition factor has been used as an index of growth and feeding intensity (Fagade, 1979). Condition factor decrease with increase in length (Bakare, 1970; Fagade, 1979); and also influences the reproductive cycle in fish (Welcome, 1979). Condition factors of different species of cichlid fishes have been reported by Siddique (1977), Fagade (1978, 1979, 1983), Dadzie and Wangila (1980), Arawomo (1992) and Oni et al. (1983). Some condition factors reported for other fish species include; Alfred-Ockiya (2000), *Chana chana* in fresh water swamps of Niger Delta and Hart (1997), *Mugil cephalus* in Bonny estuary, Hart and Abowei (2007), ten fish species from the lower Nun River, and Abowei and Davies (2009), *Clarotes lateceps* from the fresh water reaches of the lower Nun river.

The length-weight relationship of fish is an important fishery management tool. Its importance is pronounced in estimating the average weight at a given length group (Beyer, 1987) and in assessing the relative well being of a fish population (Bolger and Connoly, 1989). Consequently, length-weight studies on fish are extensive. Notable among these are the reports Shenouda et al. (1994), for Chrysichthys spp. from the Southernmost part of the River Nile (Egypt), Alfred-Ockiya and Njoku (1995) for mullet in New Calabar River, Ahmed and Saha (1996) for carps in Lake Kapital, Bangladesh, King (1996) for Nigeria fresh water fishes, Hart (1997) for *Mugil cephalus* in Bonny Estuary; Diri (2002) *Tilapia guineensis* in Elechi creek.

Catch Per Unit Effort (CPUE) is a useful index in the assessment of abundance of fish species (Gulland, 1975). It is essential in the determination of maximum sustainable yield (MSY) and potential yield. Tobor (1992) reported that the inshore waters of most parts of the West African coast are rich in fish resources in quantities that can support commercial exploitation on a sustainable
basis. However, later developments in fisheries studies have pointed to the depletion of the fish stocks (Okpanefe, 1987).

Accurate fisheries statistics in the river and its adjoining flood plains is vital for the formulation of a sound fisheries management programme in the Nkoro River and similar water bodies. But, this is completely lacking. A part from (Scott, 1966; Reed et al., 1967; Otobo, 1981; FAO, 1994; Otobo, 1993; Ita and Medahili, 1997; Sikoki and Otobotorere, 1999; Ezekiel et al., 2002; Abowei and Ezekiel, 2003; Abowei et al., 2007; Abowei and Hart, 2007; Abowei et al., 2008; Abowei and Hart, 2008; Abowei and Hart, 2009; Abowei and Davies, 2009) from different water bodies, there are no reliable data on the abundance of C. senegalensis from Nkoro River. This is essential for formulation of development plan in the fishing industry. This study therefore provides information to fill that gap in Nkoro River fisheries.

Unfortunately, no work has been done on the length-weight relationship of Ilisha africana from the Nkoro River. A study of the abundance, condition factor and length-weight relationship of I. ilisha from the Nkoro River adds more information on the family, pristigasridae to complement the existing data in the management and culture of the species in the Nkoro River, Niger Delta.

MATERIALS AND METHODS

Study Area: The Nkoro River is a distributary of the Andoni River in the Niger Delta area of Nigeria. The Nkoro River lies between latitudes 4°28′ to 4°45′ N and longitudes 7°45′ E. The Niger Delta is one of the world largest wetlands covering an area of approximately 70,000 km². The area is economically important and rich in biodiversity. Numerous activities such as oil exploration and production and agricultural activities go on in the region. Most of Nigeria’s oil and gas reserves and production; which account for over 80% federal government’s revenue, is located within the Niger Delta region. The Red and white mangroves (Rhizonhora and Avicenica spp.) mangrove swamps and flood plains border the river and its numerous creeks; and these are well exposed at low tides.

Fish Sampling: Fish specimens were procured from artisanal fishers and middlemen at their landing site for the study. Sampling of landed catches was done twice in a month for a period of twelve months The fishers used a wide range of fishing gear such as hook and line, long line, cast nets, gill nets and traps. From the catches, fish specimen were randomly identified using keys and descriptions by Holden and Reed (1972), Loveque et al. (1991) and Reed et al. (1967). Specimens were stored in coolers containing ice and transported to the laboratory for further analysis.

The condition factor (k) of the experimental fish was estimated from the relationship:

\[ K = \frac{100W}{L^3} \]  

Where \( K \) = Condition factor, \( W \) = Weight of fish, \( L \) = Length of fish (cm)

The Total Length (TL) of the fish was measured from the tip of the anterior or part of the month to the caudal fin using meter rule calibrated in centimeters. Fish were measured to the nearest centimeter. Fish weight was measured after blot drying with a piece of clean hand towel. Weighing was done with a tabletop weighing balance, to the nearest gram. The length measurements were converted into length frequencies with constant class intervals of 2cm. The mean lengths and weights of the classes were used for data analysis, the format accepted by FISAT (Gayanilo and Pauly, 1997).

The relationship between the length (L) and weight (W) of fish was expressed by equation (Pauly, 1983):

\[ W = aL^b \]  

Where

\( W \) = Weight of fish in(g)  
\( L \) = Total Length (TL) of fish in(cm)  
\( a \) = Constant (intercept)  
\( b \) = The Length exponent (slope)

The “a” and “b” values were obtained from a linear regression of the length and weight of fish. The correlation (r²), that is the degree of association between the length and weight was computed from the linear regression analysis:

\[ R = r^2 \]

Abundance was estimated from the weight (kg) of the total catch of each station for each species over the period of this study and compared for difference using Analysis of variance (ANOVA) to test for difference between the stations. Catch per unit effort was calculated by dividing the total monthly catch by the effort (number of fishers per boat) and finally dividing by the number of hours of fishing giving:

\[ CPUE = \frac{\text{Total catch/No. of fishers/fishing hours}}{\text{Kg/man/h}} \]  

where CPUE = Kg/man/h (King, 1991).

The figures for catch per unit effort were tested for variation on monthly and station basis using ANOVA.

RESULTS

Table 1 expresses the condition factor and the exponential equation from the length weight relationship.

Fig 1: Monthly condition factor for *I. africana*

of *Ilisha africana* in Nkoro River. From a sample size of 113 specimens, K value was 0.999 and the exponential equation was \( Wt = 0.05998 \times (TL)^{1.12} \), indicating an isometric growth pattern.

The monthly catch per unit effort for *Ilisha africana* in Nkoro River is presented in Table 2. The highest catch was recorded in February (1.61), followed by March (1.00), January (0.90), December (0.60) and June (0.10). April, May, July, August, September, October and November recorded no catch during the study.

Fig 1 shows the monthly condition factor for *I. africana* in Nkoro River. The highest condition factor value (1.58) was recorded in February and the lowest (0.00) in September.

The catch per unit effort of *Ilisha africana* at each station in Nkoro River is presented in Table 3. The highest catch per unit effort (1.13) was recorded in stations 2 and 4, followed by station 1 (1.12) and station 3 (0.72 each).

**DISCUSSION**

The mean condition factors 0.999 and monthly condition factor ranging from 0.4 – 1.61 obtained in this study varied slightly with the results from other studies. Ajayi (1982), reported \( K = 0.77 – 0.81 \) for *Clarotes filamentosus* in lake Oguta; Nwadiaro and Okorie (1985) obtained \( K = 0.49-1.48 \) in Andoni river. The value obtained from the study showed that all species studied were in good condition. Gayamilo and Pauyl (1997) reported that certain factors often affect the well-being of a fish. These include: data pulling, sorting into classes, sex, stages of maturity and state of the stomach.

The condition factor (K) reflects, through its variations, information on the physiological state of the fish in relation to its welfare. From a nutritional point of view, there is the accumulation of fat and gonad development (LeCren, 1951). From a reproductive point of view, the highest K values are reached in some species (Angelescu *et al*., 1958). K also gives information when comparing two populations living in certain feeding, density, climate, and other conditions; when determining the period of gonad maturation; and when following up the degree of feeding activity of a species to verify whether it is making good use of its feeding source (Weatherley, 1972). From the above assertions we could conclude that the five species in this work reproduce between May to October since they recorded the lowest K at about this period.

Furthermore, Vazzoler (1996) confirmed that lowest K values during the more developed gonad stages might mean resource transfer to the gonads during the reproductive period. Braga (1986), through other authors, showed that values of the condition factor vary according to seasons and are influenced by environmental conditions. The same may be occurring in the environment under study since the floodplain is influenced by many biotic and abiotic factors, which favor the equilibrium of all the species in the ecosystem.

The values obtained for the weight – length relationship (\( Wt = 0.05998 \times (TL)^{1.12} \)) showed that *Ilisha africana* was isometric in growth. Several authors have reported both isometric and allometric growth for different fish species from various water bodies. King (1991), reported allometric growth patterns for Tilapia species from Umouseriche lake. King (1996) reported isometric growth for *Pseudotolitthus elongatus* from Qua Iboe estuary. Ekeng (1990) also reported an isometric growth pattern for *Etmalosa fimbriate* from Cross River estuary in Cross River state. Marcus (1984), obtained an isometric growth patterns for *E. fimbriate* from coastal and brackish water of Akwa Ibom state. Sheneuda *et al.* (1994) also observed an isometric growth patterns for *Chysichthys auratus* from the southernmost parts of River Nile and Egypt.

The transformed length fitted over weight gave linear growth indicating the three dimensional growth structures of most fish species (Lagler *et al.*, 1977). Values of the length exponent in the length-weight relationship being isometric implies that the fish species did not increase in weight faster than the cube of their total lengths. However, the weight of the rest species increased faster than the cube of their total lengths.

Length-weight relationships give information on the condition and growth patterns of fish (Bugenal and Tesch, 1978). Fish are said to exhibit isometric growth when length increases in equal proportions with body weight for constant specific gravity. The regression co-efficient for
isometric growth is ‘3’ and values greater or lesser than ‘3’ indicate allometric growth (Gayanilo and Pauly, 1997).

The catch per unit data February (1.61), followed by March (1.00), January (0.90), December (0.60) and June (0.10) obtained from this study; varied from the results obtained from other studies. Scott (1966) reported that, rivers, lakes and swamps of the Niger Delta produced about 2,000 tonnes of fish per year. Moses (1981) estimated a mean annual catch of 4,791 tonnes from the cross river over a period of twelve years. Sikoki and Hart (1999) in the Brass river, estimated the total biomass of 160.20 of fish per boat, total catch of 254,554 kg, annual production of 610.93 tonnes, estimated mean catch per boat of 384.90 kg and a standing stock of 1.19 km⁻³.

Variation in the total estimate values in Nkoro River could be attributed to differences in fishing and industrial activities in the different rivers. The reason for the low estimates in the Nkoro River could be as a result of high mortality of both juveniles and brood stock of various fish species as a result of predatory activities, which is typical of the study area. A similar remark was made by, Ssentengo et al. (1986). Satia (1990) also noted the controversy surrounding fish production statistics. In the lower Nun River, much of the problem hampering the acquisition of reasonably accurate fisheries statistics and resource appraisal appear to stem mainly from lack of, or inadequate investment and lack of trained personnel to handle data collection.

Factors affecting fish distribution and abundance have already been reported by different workers. Availability of food, spawning rates, breeding grounds coupled with shelter, presence of current, vegetation, depth of water, breeding habits migration and low predation have been suggested as major limiting factors affecting the distribution and abundance of various fish families in Kainji Lake (Ita, 1978).

Angelescu et al. (1958) reported fish catch varied with type of gear used, tidal condition and period of capture, diurnally and seasonally. From the work of King (1991), it is clear that most commercially and scientifically important fish species occurring in the Niger Delta waters can be landed all year round by artisanal fishers but there are months when they are more abundant.
