Effect of Potato Flakes as Fat Replacer on the Quality Attributes of Low-Fat Beef Patties

1Rehab F.M. Ali, 2A.M. El-Anany and 2A.M. Gaafar
1Department of Biochemistry, Faculty of Agriculture, Cairo University, 12613, Giza, Egypt
2Special Food and Nutrition Department, Food Technology Research Institute, Agricultural Research Center, Giza, Egypt

Abstract: The objective of this study was to evaluate the chemical, physical and sensory characteristics of low-fat beef patties formulated by replacing different levels (25, 50, 75 and 100%) of fat with hydrated potato flakes. Uncooked and cooked beef patties formulated with potato flakes had higher (p<0.05) moisture, carbohydrate and ash content and lower (p<0.05) fat contents than that of the control. Caloric values of beef patties was lower (p<0.05) than control by between 7 and 57%, cholesterol content of patties decreased as level of potato flakes increased. Cooking yield, Water Holding Capacity (WHC) as well as moisture and fat retention were increased significantly (p<0.05) with increasing the levels of potato flakes. Overall acceptability values for beef patties formulated with potato flakes were higher (p<0.05) than the control samples. Beef patties formulated with 75% potato flakes as fat replacer had significantly (p<0.05) the highest score of overall acceptability. Hydrated potato flak could be an excellent replacement for fat in beef patties maintaining acceptable and desirable sensory properties.

Key words: Beef burger, caloric value, cholesterol, colour, flakes, sensory

INTRODUCTION

The consumption of convenience foods in the restaurants such as beef or chicken burgers is increasing now. These products should contain 20-30% of fat to give the desirable succulence and texture (Wilson et al., 1981). The fat of beef burger is characterized by its high content of saturated fatty acids, and cholesterol which are associated with cardiovascular diseases (Oh et al., 2005), some types of cancer (Smith-Warner and Stampfer, 2007.) and obesity (Howarth et al., 2005; Fernandez-Gines et al., 2005). Due to the meat and meat products lead to certain diseases, the meat industry has been worst hit by adverse publicity. The role of fat as one of the main causes of cardiovascular disease has been well documented (Rossum et al., 2000). Fat, trans Fatty Acids (FAs), cholesterol and saturated FAs of meat products have also been associated with obesity and cancers (especially colon, prostate and breast) in developing countries (Slattery et al., 1999; Grundy, 1994). Extensive researches have been performed on fat replacement to improve quality of many products (Jimenez, 2000; Allen et al., 1999; Lucca and Tepper, 1994). Fat content has a basic effect on various physicochemical and sensory characteristics as flavour, mouthfeel, juiciness, texture, handling, bite, heat transfer etc.) (Pearson and Gillett, 1999) and it can not be modified and/or reduced with improper less fat or another type of fat. The food industry has responded to consumer demand by offering an ever-increasing variety of low-fat meat choices. To achieve healthy meat products, it is recommended to reduce high fat content to appropriate limits and increase the levels of other substances with beneficial properties (Jo et al., 2003; Arihara, 2006). With the growing need for products with less fat or calorie content, it becomes necessary to develop meat products that are pertinent to consumer demand. Several studies have demonstrated possible use of different sources of starch and food hydrocolloids such as carrageenan, cellulose gum, konjac flour, guar gum , xanthan gum as fat replacements or the use of poultry meat as replacement for red meat in reduced-fat meat products (Troutt et al., 1992; Osburn and Keeton, 1994; Mansour and Khalil, 1997; Chin et al., 1998; Khalil, 2000; Mansour, 2003; Andrés et al., 2006; Bhattacharyya et al., 2007; El-Beltagy et al., 2007). Vegetable products added to raw or cooked meat products to improve its functional properties, minimize the product cost and improving

1: All treatments were formulated with 2 g salt, 1.5 g spices mixture, 1 g sugar, 0.2 g tripolyphosphate, 0.3 g ascorbic acid; 2: potato flakes were rehydrated with water, potato flakes /water (1:5, w/v)

Materials:
- Fresh lean beef and kidney fat were obtained from the slaughterhouse in Giza, Egypt. Lean beef samples were obtained from boneless rounds and trimmed from all subcutaneous and intermuscular fat as well as thick, visible connective tissue.
- Potato flakes (moisture content = 7%) was provided by Teba for food industry, Alexandria Borg el Arab new city part 8 bluke 11, Egypt
- Tripolyphosphate was purchased from El-Gomhoria Co. for trading Medicines, Chemical & Medical Appliances El-Sawah St., Amireya-Cairo, Egypt.
- Salt, sugar and spice mixture were obtained from local market in Giza, Egypt.

Methods:
- **Formulation of beef patties:** The lean beef and kidney fat sources were separately ground in meat grinder (Moulinex 505, France). Fat content of the lean and fat portions were determined prior to the manufacture of beef patties. The lean beef (4% fat), kidney fat (90% fat), potato powder and water were used to formulate the beef patties (Table 1). The control patties were formulated to contain 65% lean beef and 20% kidney fat. Different levels of kidney fat (25, 50, 75 and 100%) were replaced by equal amounts of rehydrated potato flakes. Appropriate amounts of each formulation were mixed by hand, subjected to final grinding (0.5 cm plate) and processed into patties (100 g weight, 1.2 cm thick and 10 cm diameter). Patties were placed on plastic foam meat trays, wrapped with polyethylene film and kept frozen at -18°C until further analysis.

Cooking procedure: Frozen patties were cooked in a preheated (148°C) electric oven (VEN MLW Medizinische, Greate, Berlin, Germany) which was standardized for temperature. The patties were cooked 6 min, turned over, cooked 6 min, turned again and cooked 4 min. The patties were weighed before and after cooking to determine percentage cooking yield as follows:

\[
\text{Cooking yield (\%)} = \frac{\text{Weight of cooked patty}}{\text{Weight of uncooked patty}} \times 100
\]
Proximate composition: Moisture, ash, crude protein and fat of uncooked and cooked patties were determined according to AOAC, 930.04, 930.05, 955.04, (2000) and Blight and Dyer (1959) methods, respectively. Carbohydrates was calculated by differences. All determinations were performed in triplicate (two determination for each replicate). Percentage of moisture and fat retention during cooking was calculated according to Khalil (2000) as follows:

\[
\text{Moisture retention (\%)} = \left( \frac{\text{Cooked weight} \times \text{Moisture in cooked patties (\%)} }{\text{Uncooked weight} \times \text{Moisture in uncooked patties (\%)}} \right) \times 100
\]

\[
\text{Fat retention (\%)} = \left( \frac{\text{Cooked weight} \times \text{Fat in cooked patties (\%)} }{\text{Uncooked weight} \times \text{Fat in uncooked patties (\%)}} \right) \times 100
\]

Caloric values: Total calorie (Kcal) for uncooked and cooked patties were calculated on the basis of 100 g sample using Atwater values for fat (9 Kcal/g), protein (4.02 Kcal/g) and carbohydrates (3.87 Kcal/g) as described by Mansour and Khalil (1997).

pH and water holding capacity (WHC): The pH values of raw patties (aliquots of 10 g/90 mL distilled water) were determined at room temperature (~25°C) using a digital pH meter (model MP 220, Mettler Toledo, USA). The Tsai and Ockerman (1981) press technique was used to measure the water holding capacity of raw patties. Raw patty (0.5 g) was placed on filter paper (Whatman No. 1, stored over night in saturated KCl) which was placed between tow glass sheets and pressed for 20 min by a 1 kg weight. The area of free water was measured using a compensating polar planimeter and the WHC was calculated as follows:

\[
\text{Free water (\%)} = \left( \frac{\text{Total surface area} - \text{meat film area, mm} (6.11)}{\text{Total moisture (mg) in meat sample}} \right) \times 100
\]

\[
\text{WHC (\%)} = 100 - \text{free water}
\]

Cholesterol assay: Cholesterol content was determined by the procedure described by Rhee et al. (1982) with the following slight modification for saponification: an aliquot of lipid extract (containing no more than 0.12 g lipid) was freed from the solvent and saponified with 10 mL of 150 g/L KOH (in 900 mL/L ethanol) for 10 min in an 88°C shaking water bath. When cooled, 5 mL of distilled water was added and unsaponifiable material was extracted once with 10 mL hexane.

Colour evaluation: The colour of raw and cooked patties was determined using a colourimeter (CR-400, Minolta, Japan). Colour values (lightness (L*), redness (a*), yellowness (b*), saturation index and hue angle were measured on surface of beef patties. The mean of five measurements was taken for each value.

Sensory evaluation: Sensory evaluation of cooked patties was performed according to Khalil (2000) by ten trained panelists who were staff of Food Technology Research Institute, Agriculture Research Center, Giza, Egypt. Cooked samples were cut into 4 equal-sized wedges and served at approximately 50°C and served randomly to each panelist. Samples were presented in paper plates coded with 3-digit random numbers. Patties were evaluated for tenderness, juiciness, flavour intensity, connective tissue, and overall palatability. An eight-point scale was used where 1 = extremely tough, dry, devoid of ground beef flavour and abundant in connective tissue and 8 = extremely tender, juicy, intense in ground beef flavour and absence of connective tissue. Water was provided, so that panelists could cleanse their palates between samples.

Statistical analysis: Data were statistically analyzed in completely randomized design in factorial arrangement according to the procedures outlined by Gomez and Gomez (1984) and the treatments means were compared by least significant differences (L.S.D) and Duncan multiple range using SPSS program package.

RESULTS AND DISCUSSION

Proximate composition: The proximate composition of uncooked and cooked patties as affected by the addition of hydrated potato flakes instead of fat is presented in Table 2. Uncooked and cooked beef patties formulated with different levels of hydrated potato flakes had significantly (p≤0.05) higher moisture content than that of control. As fat replacement level increased moisture contents significantly (p≤0.05) increased. This could be attributed to the ability of fat replacer to bind water (Mansour, 2003; Khalil, 2000; Bullock et al., 1995; Berry and Wergin, 1993). Cooking process caused reduction in moisture content, this reduction is attributed to the releasing of water, which was not bound tightly by proteins or hydrated potato flakes during cooking process (Ell-Beltagy et al., 2007; Mansour, 2003; Khalil, 2000). However beef patties formulated with hydrated potato...
flakes at any fat replacement level lost significantly (p<0.05) less moisture during cooking than control, this could be explained as due to increased the water holding capacity of the ingredients to bind water (Mansour and Khalil, 1997). In this respect Mansour (2003) showed that patties formulated with corn starch, tapioca starch lost less moisture during cooking process than control samples. Control beef patties had higher fat content than those formulated with different levels of hydrated potato flakes. As expected fat content of uncooked and cooked beef patties decreased significantly (p<0.05) with increasing of potato flakes levels. When the beef patties were cooked, fat content tended to increase consistent with the level of hydrated potato flakes in low-fat beef patties and decrease in control. Fat was more easily removed from higher fat patties because of a greater probability of encounter and expansion of fat droplets (Tornberg et al., 1989).

Replacement of fat with different levels of hydrated potato flakes resulted in significant (p<0.05) increase in carbohydrates and ash of uncooked and cooked beef patties. Concerning to calories content, data showed that as fat content decreased or level of hydrated potato flakes increased, in both uncooked and cooked patties, total calories declined (Table 2). Reduction rates in calories content of uncooked patties formulated with different levels of hydrated potato flakes ranged from 17.41 to 56.98%. While, it ranged from 6.97 to 47.29% for cooked patties compared with their control. Caloric reduction positively correlated with fat reduction (El-Beltagy et al., 2007; Mansour, 2003; Khalil, 2000; Mansour and Khalil, 1997; Osburn and Keeton, 1994).

These results indicated that formulation patties with hydrated potato flakes considered a good method for caloric reduction which is very important for consumers restricted for their fat intake.

pH, Cooking yield, Water holding capacity (WHC) and Moisture and fat relation: The pH value of low-fat beef patties were not significantly affected (p>0.05) by the level of fat replaced (potato flakes) (Table 3). Cooking yield was significantly (p<0.05) improved by adding various levels of potato flakes. This improvement could be due to the increased in moisture binding by the added potato flakes. Control samples had significantly the lowest cooking yield was (61.25). This loss in control beef patties might be attributed to the excessive fat

<sup>a</sup> Each value in the table is the mean of three replicates and two determinations were conducted for each replicate; Means in the same column with different letters are significantly different (p<0.005)
separation and water release during cooking (Mansour and Khalil, 1999; Cross et al., 1980; Troutt et al., 1992; Trius et al., 1994). However, beef patties formulated with 100% potato flakes, had significantly (p<0.05) the highest cooking yield was (78.91%). Generally, as the fat replacement level increased, the cooking yield increased (p<0.05). Starches have been shown to be effective water binders and to improve cooking yield in beef patties (Mansour, 2003; Khalil, 2000; Berry, 1997).

The Water holding capacity (WHC) was increased significantly (p<0.05) with increasing the levels of potato flakes. Control samples had significantly (p<0.05) the lowest value of (WHC) was 60.75% whereas the highest (p<0.05) WHC was observed in beef patties formulated with 100% potato flakes as fat replaces (79.90%) followed by samples formulated by 75% potato flack (74.45%). This increase in water holding capacity may be due to the ability of starch in potato flack to absorb and keep more of water. The ability of potato flakes to hold moisture in meat samples has favorable implications in the final product quality by preventing excessive moisture loss in products thus avoiding undesirable crunchy and flaky texture.

Significant increases in moisture retention were noticed in beef patties formulated with various levels of potato flakes compared with control. Beef patties formulated with 100% potato flakes had significantly (p<0.05) the highest moisture retention was 91.40% whereas control samples had the lowest retention of moisture was 54.69. Addition different levels of starch led to increase the retention of moisture in beef patties (El-Beltagy, 2007; Mansour and Khalil, 1997). Increasing the levels of potato flack (as fat replaces) resulted in significant (p<0.05) increase in fat retention as a result of cooking. Control samples had significantly (p<0.05) the lowest value of fat retention was 59.60% whereas the highest (p<0.05) values of fat retention were observed in beef patties formulated with 100% potato flakes as fat replaces (91.40% ) followed by samples formulated by 75% potato flakes as fat replaces (82.20%). Tornberg et al. (1989) concluded that fat was more easily removed from higher fat patties because of a greater probability of encounter and expansion of fat droplets. Also, they further concluded that the dense meat protein matrix of low-fat ground beef prevented fat migration. In this regard Hoelscher et al. (1987) and Khalil (2000) showed that at 100% fat replacement level by modified corn starch, beef patties had positive retention (130-183%) of initial fat.

### Cholesterol content:
Cholesterol content for uncooked and cooked beef patties are presented in Table 4. Data showed that Cholesterol content of uncooked and cooked control sample (full fat) was significantly (p<0.05) the highest values were 177.9 and 202.5 g/kg as wet and dry weight basis respectively, this may have been caused by a high level of fat in control samples which resulted in an increase in cholesterol content. Whereas uncooked beef patties formulated with 100% potato flakes had significantly (p<0.05) the lowest values of Cholesterol content were 125.04 and 121.33 g/kg as wet and dry weight basis, respectively. Generally, cholesterol content of uncooked and cooked beef patties decreased significantly (p<0.05) as level of potato flakes as fat replaces increased. This decrease in cholesterol content was proportional to the increase in potato flack levels. Cholesterol content of row beef patties decreased as the amount of fat replaces increased and also decreased as the fat content decreased (Rhee and Smith, 1983; Mansour and Khalil, 1999). The cholesterol content of cooked beef patties was higher than that of uncooked beef patties when expressed either on a wet or dry weight basis. It should be pointed out that cholesterol did not increased due to cooking; cooking reduced the weight of the uncooked beef patties, making the cholesterol content g⁻¹ of the cooked beef patties higher than that in an equivalent weight of uncooked beef patties (Mansour and Khalil, 1999). In this regard Kowale et al. (1996) reported that all burger formulations recorded significantly higher cholesterol content upon cooking. This observation may be due to loss of moisture during cooking.

### Colour evaluation:
Colour attributes of row and cooked low-fat beef patties are presented in (Table 5). L* values

Sensory evaluation: Sensory properties of beef patties are presented in Table 6. Data show that beef patties formulated with various levels of hydrated potato flakes as fat replacer were significantly higher (p<0.05) in juiciness than control. Control samples (full fat) had significantly (p<0.05) the lowest value of juiciness 5.4, whereas, patties formulated with either 75 and 100% hydrated potato flakes as fat replacer had significantly (p<0.05) the highest values were 7.2 and 7.4, respectively. The improved water holding capacity (Table 3) by using hydrated potato flakes could be detected through increased juiciness. The results of Khalil (2000) and Mansour (2003) indicated increased the juiciness of beef patties by using starches. No significant (p>0.05) effects in flavour intensity were observed in beef patties formulated by potato flack and control sample except at 100% fat replacement which showed significant (p<0.05) reduction in flavour intensity value, this reduction ay due to the presence of starchy flavour. Several studies have indicated decreased flavour intensity of beef patties by using starch or gums sources at 100% as fat replacers (Brewer et al., 1992; Troutt et al., 1992; Khalil, 2000; Mansour, 2003). Low-fat beef patties had higher (p<0.05) sensory ratings for juiciness than control. Control samples (full fat) had significantly (p<0.05) the lowest value of juiciness was 5.4, whereas, patties formulated with either 75 and 100% hydrated potato flakes as fat replacer had significantly (p<0.05) the highest values were 7.2 and 7.4, respectively. The improved water holding capacity (Table 3) by using hydrated potato flakes could be detected through increased juiciness. The results of Khalil (2000) and Mansour (2003) indicated increased the juiciness of beef patties by using starches. No significant (p>0.05) effects in flavour intensity were observed in beef patties formulated by potato flack and control sample except at 100% fat replacement which showed significant (p<0.05) reduction in flavour intensity value, this reduction ay due to the presence of starchy flavour. Several studies have indicated decreased flavour intensity of beef patties by using starch or gums sources at 100% as fat replacers (Brewer et al., 1992; Troutt et al., 1992; Khalil, 2000; Mansour, 2003). The values of Connective tissue in beef patties were not significantly (p>0.05) affected by replacing fat with potato flakes. Concerning to overall acceptability values for beef patties formulated with potato flakes were higher (p<0.05) than the control samples. Beef patties formulated with 75% potato flakes as fat replacer had significantly (p<0.05) the highest score of overall acceptability was 6.5.
In conclusion, the addition of hydrated potato flakes reduced the cholesterol content of beef patties by between 2.1 and 29.3% for uncooked beef patties and between 7.0 and 39.9% for cooked. In the same time the calories value was reduced by 17.4 to 47.5 and 6.9 to 46.9 for uncooked and cooked beef patties, respectively. Hydrated potato flack could be an excellent replacement for fat in beef patties maintaining acceptable and desirable sensory properties.

ACKNOWLEDGMENT

First of all thanks to Allah, the almighty God who had given us the strength to further my study. We would like to convey my heartiest thank and appreciation to Dr. Gamal. Fathy Hassan, Horticulture Research Institute; Agricultural Research Center, Giza, Egypt. We grateful to our families for them everlasting support and courage.
